I am new to gRPC and was wondering if this is possible to be done using gRPC. I have a typical HTTP request/response pattern where a http request is made with a particular method to the http server and it responds with the content that was received. Say for example, I have a route of /path/to/url/ (http server example), and as per the protocol, if the request is to /path/to/url/userid then it should be returned to the client with a 404 Not Found response with text User not Found. But the problem I am facing is that my route that serves http calls has a separate pool of web servers. We need a separate pool to support on-line dynamic scaling. The pool of servers have a mean time to live (MTT) which is stored in memcached. So, we would like to have a request routing strategy so that when a server in the pool goes down, and any requests that are intended to go to that server goes to the first server in the pool, and to that server if the server cannot process the request, it should return a generic 500 Server Error response. This means that we cannot have a pool of web servers that respond to all the possible http requests. Is there a way where I can modify the request routing strategy on the server so that it responds with a 500 Server Error (using a gRPC server) if the request is invalid. But since it has to be a client-initiated request, it will not be dropped by the client when it goes to the next server. So for example, say the original request is 6d1f23a050
